Abstract Clay soil is the foundation for many buildings. Some families have the characteristic to be swelling or shrink. However, construction on this type of soil requires a good companion for the recognition of identification and characterization of their swelling potential. In this work we are interested by two aspects: -The first is on the tests recommended for the identification of four expansive soils in the region of Tlemcen (Algeria); -The second is to assess the influence of the addition of milk of lime and mineral salts (KCl Potassium Chloride, Magnesium Chloride MgCl2) at different percentages on the physico-chemical parameters, the swelling potential of these soils from correlations approximate estimates. The results obtained show that stabilization by the addition of milk of lime modifies the physico-chemical characteristics of soil and the results are quite satisfactory in significantly reducing the phenomena of swelling, as regards stabilization with milk of lime we note that the salt concentration has little influence on the potential of swelling and it differs from one another salt.

Keywords Clay, Milk of lime, Swelling, Stabilization, Salts, KCl, MgCl2

1. Introduction

Excessive heave, settlement, low shear strength, and internal erosion of soils can cause damage to engineering structures. In order to overcome these difficulties and to prevent structural damages during the site selection and/or construction stages, engineers have developed several techniques. They avoid potential soil problems by selecting an alternative site or by removing the undesirable soil and replacing it with desirable soil.

Engineering designs have been adopted for the conditions at hand, lastly the soil can be improved. The last approach, improvement or stabilization of a soil, is becoming the more attractive method for the soil engineers.

Stabilization of clay soils using lime, cement, salts has long been used to improve the workability and mechanical characteristics of the soils in geotechnical engineering[5].

Some attempts have shown that the addition of a material such as salts or the milk of lime appearance modifies the physico-chemical parameters, and reduced the swelling in a remarkable manner.

This result has to consider the addition of this type of material is a technique of stabilization promising. This concept is the subject of this study.

2. Localization of the Site and Geotechnical Identification

The soils objects of this study are reworked clays coming from different regions of Tlemcen (north west of Algeria), in an active area of swelling perspective (figure1).

Whatever the objectives sought in geotechnical study, the rule is to make initial identification of concerned soils. This procedure is used to guide further geotechnical analysis and especially to make a classification of encountered materials. The parameters required for this classification are both physico-chemical and granulometric.

The results of all tests performed on the four soils studied are listed in Table 1:

3. The Mineralogy Structure of Clay Expansive

It is necessary to present the crystallographic structures of different families of clay (common) to better understand relations between water and clay.

Clays and micas are part of the family of phyllo silicates. The crystal lattice of phyllo silicates is based on an array of SiO4 tetrahedra (Figure 2). Each tetrahedron SiO4 tetrahedra sharing 3 sommets with neighbors; vertex set is a shared assembly hexagonal plane. The apex tetrahedron that is not in the plan is shared an octahedron AlO6 (Figure 2). It is the combination of tetrahedral layers (T) and octahedral layers (O) which is the justification of the crystal lattice each of clay.

4. Classification of Expansive Soils

Carry out a proper classification of expansive soils implies that the geotechnical parameters are known representative of the swelling. The problem lies in the definition of these parameters[13]. Practice has it that the pressure and the
magnitude of swelling that are used to characterize expansive soils.

The literature contains a considerable number of empirical approaches that assess the swelling potential of soils. Some authors believe this potential link to a single parameter. Thus, as shown in Table 2, below, Altmeyer, Ranganathan and Satyanarayan [3], and Snethen [3] propose classifications which give respectively the swelling potential depending WR, IR, IP (Table 3).

5. Correlation Between Swelling and Physico-Chemical Parameters

To test the comparison of the classifications listed above, they have been applied to soil samples from sites of Tlemcen. The identifications are given in Table 4.

Of these classifications, there emerges the following remarks:

Some classifications like that of Altmeyer tend to overestimate the swelling potential of soils as it provides all the samples as highly expansive.

The various classifications do not converge to the same qualification for the same sample. These contradictions find their explanation in the number and nature of the parameters taken into account by each of these classifications. It should be noted that the determining parameters in the expansive character of a soil are known. By cons, the influence of each parameter in this expansive is difficult to quantify.

6. Physics-Chemical Variation of The parameters According to Percentages of Milk of Lime

![Diagram](image.png)

The swelling of soils is sometimes correlated with some physico-chemical parameters in order to study the influence of stabilization on these parameters, measurements of Atterberg limits and VBS were made with milk of lime at different percentages.

Figure 4 shows the path followed by the clays of Tlemcen after treatment with 2% -4% -6% - 8% milk of lime.

We notice that the clays which high plasticity seen after treatment with milk of lime, consistence progress to low plasticity. This change in the consistence related to the percentage of milk of lime, translates into a decrease of plasticity index which partly due to ionic reactions of milk of lime (excess of cations calcium) with clay minerals which causes a flocculation of the soil, and partly by an exchange of calcium with other cations in the structure of the clay. We also note a continued decrease in blue value and the index of shrinkage according to the increased percentage of milk of lime.

7. Correlation between Physicochemical Parameters and Swelling after Using 8% of Milk of Lime

A correlation between physicochemical parameters and swelling occurred after the use of 8% of milk of lime, we see that the swelling is reduced after the use of milk of lime, For example for the soil 1 according to the classification of Holtz is a past from a high potential to medium potential (table 5).

8. Action of Mineral Salts on the Physicochemical Parameters of Studied Soils

We have conducted a study on the effect of salts on the physical-chemical parameters this study is addressed to four soils.

Tables 6, 7 represent the variation of physicochemical parameters depending of salt Concentrations (0.05, 0.1, 0.2 mol/l) for different types of salts (KCl, MgCl2).

The results show that the influence of salts on the physicochemical parameters depends on the nature the salts used and their concentrations.

Compared to KCl, magnesium chloride has the effect of decreasing over the liquid limit and plasticity index and the blue value.

The salts may increase the withdrawal limits and this is of course reduces the potential swelling.

9. Conclusions

This study has helped to define and measure characteristics mineralogical, chemical, Physical and soil granulometric in the region of Tlemcen.

In this context, it was shown that from simple tests performed in practically all campaigns preliminary reconnaissances, it is possible to qualitatively identify expansive soils and to obtain correlations from approximate estimates of swelling.

The results obtained on the addition of lime milk show that treatment of soils with milk of lime modifies the physicochemical characteristics of soil and the results are quite satisfactory in considerably reducing the phenomenon of swelling, and can be a solution to consider.

The mineral salts change the physicochemical characteristics soils studied, compared with milk of lime, salt concentration has little effect on the swelling and it depends on the nature of the salts and their concentrations.
